

Thursday 24th October

I can explore how water changes state.

I can see condensation on the window because the water is heated and is evaporated and then turned into again then turned into a water vapour. The little spots of water is the temperature that is coming out of the cup and because the windows cold its getting condensation. It's a reversible changes because the water is warm then if you leave it it goes cold which will cool down the temperature is lower so less condensation.

Your explanation shows some understanding of the changes.
